# Proficiency Testing <br> Microbiology - Food 

## October 2017

Accred. no. 1457
Proficiency testing ISO/IEC 17043

## Quantitative analyses

- Aerobic microorganisms, $30^{\circ} \mathrm{C}$
- Aerobic microorganisms, $20^{\circ} \mathrm{C}$
- Contaminating microorganisms in dairy products
- Enterobacteriaceae
- Coliform bacteria $30^{\circ} \mathrm{C}$
- Coliform bacteria $37^{\circ} \mathrm{C}$
- Thermotolerant coliform bacteria
- Escherichia coli
- Presumptive Bacillus cereus
- Coagulase-positive staphylococci
- Enterococci

## Qualitative analyses

- Gram-negative bacteria in pasteurized dairy products

## Abbreviations

## Media

| BA | Blood agar |
| :--- | :--- |
| CBC | Oxoid BrillianceTM Bacillus cereus agar |
| BEA | Bile Esculin Agar |
| BcsA | Bacillus cereus selective Agar |
| BGLB | Brilliant Green Lactose Bile broth |
| BP | Baird-Parker agar |
| COMPASS | COMPASS Enterococcus agar |
| EC | E. coli broth |
| ENT | Slanetz \& Bartley Enterococcus agar |
| IA | Iron Agar |
| KEAA | Kanamycin Esculin Azide Agar |
| LSB | Lauryl Sulphate Broth |
| LTLSB | Lactose Tryptone Lauryl Sulphate Broth |

## General information on results evaluation

## Statistical evaluation of the results

Highly deviating values that did not belong to a strictly normal distribution after $\log _{10}$ transformation were identified as statistical outliers (Grubbs’ test modified by Kelly (1)). In some cases, subjective adjustments were made to set limits, based on knowledge of the mixture's contents. Outliers and false results were not included in the calculations of means and standard deviations. Results reported as "> value" were excluded from the evaluation. Results reported as "< value" were interpreted as being zero (negative result). In cases where "Pos" and "Neg" were reported for quantitative analyses, they were treated as $>1$ and $<1$ respectively. All reported results are presented in Annex 1.
According to EN ISO/IEC 17043, for which the proficiency testing programme is accredited, it is mandatory for the participating laboratories to report method information for all their analyses. Method information is sometimes difficult to interpret, since many laboratories report a medium that that is not included in the standard method that they refer to. Results from laboratories that report contradictory data on methods/media have either been excluded from the method analysis, or been added to the group of "Others", together with results from methods and media that are only used by 1-2 laboratories.

Mean values and standard deviations are normally provided for the different analyses. When the total number of reported results for an analysis is fewer than 20 , the median is provided instead of the mean value. For method groups with fewer than 5 results, only the number of false results and outliers are provided.

## Uncertainty of measurement for the assigned values

The uncertainty of measurement for an assigned value is calculated as the standard deviation divided by the square root of the number of correct results ("standard error"). The assigned value of evaluated parameters is the mean value of the participants results.

## Table and figure legends

## Tables

N number of laboratories that performed the analysis
n number of laboratories with satisfactory result
$\mathrm{m} \quad$ mean value in $\log _{10} \mathrm{cfu} / \mathrm{ml}$ (false results and outliers excluded)
s standard deviation
F number of false positive or false negative results
< number of low outliers
> number of high outliers
$\square$ global results for the analysis

## Figures

Histograms of the analytical results for each mixture are presented. The mean value of the analysis results is indicated in each histogram.

- values within the interval of acceptance (Annex 1)
- outliers
$\square \quad$ false negative results
* values outside of the $x$-axis scale

## Results of the PT round October 2017

## General outcome

Samples were sent to 189 laboratories, 49 in Sweden, 123 in other European countries, and 17 outside Europe. Of the 176 laboratories that reported results, 68 (39 \%) provided at least one result that received an annotation. In the previous round with similar analyses (October 2016), the proportion was 50 \%.

Individual results for each analysis in the PT round are listed in Annex 1 and are also available on the website after logging in: www2.slv.se/absint.

Table 1 Microorganisms in each mixture and \% of deviating results (N: number of reported results, F\%: false positive or false negative, X\%: outliers).

- no target organism or no value; (microorganism) false positive before confirmation
* the results are not evaluated

## Aerobic microorganisms, $20^{\circ} \mathrm{C}$ and $30^{\circ} \mathrm{C}$

## Mixture A

The strains of Micrococcus sp., Klebsiella pneumoniae and Enterococcus hirae were target organisms for the analysis both at $20^{\circ} \mathrm{C}$ and at $30^{\circ} \mathrm{C}$. The analyses were without problem for the majority of the laboratories, and the results were distributed around a distinct peak at both temperatures. No outliers or false negative results were reported for the analysis at $20^{\circ} \mathrm{C}$, but for the analysis at $30^{\circ} \mathrm{C}$ four low and six high outliers were reported. One laboratory reported a false negative result at $30^{\circ} \mathrm{C}$.

## Mixture B

The strains of Escherichia coli, Serratia marcescens and Staphylococcus hyicus were target organisms for the analysis both at $20^{\circ} \mathrm{C}$ and at $30^{\circ} \mathrm{C}$. The analyses were without problem for the majority of the laboratories, and the results were distributed around a distinct peak at both temperatures. No outliers or false negative results were reported for the analysis at $20^{\circ} \mathrm{C}$. For the analysis at $30^{\circ} \mathrm{C}$ two low and three high outliers were reported, but no false negative results.

## Mixture C

The strains of Providencia alcalifaciens, Staphylococcus aureus and Bacillus cereus were target organisms for the analysis both at $20^{\circ} \mathrm{C}$ and at $30^{\circ} \mathrm{C}$. The analyses were without problem for the majority of the laboratories, and the results were distributed around a distinct peak at both temperatures. No outliers or false negative results were reported for the analysis at $20^{\circ} \mathrm{C}$. For the analysis at $30^{\circ} \mathrm{C}$ one high and three low outliers were reported, but no false negative results.

## General remarks

The analyses were as a whole without problems for the laboratories. The choice of method or media had no effect on the outcome for either of the mixtures. Outliers and false negative results could not be attributed to the use of a specific method or media.

As in previous proficiency testing rounds, most laboratories followed either NMKL 86 or ISO 4833. Both methods recommend the use of Plate Count Agar (PCA), which was the most common media, followed by $3 \mathrm{M}^{\mathrm{TM}}$ Petrifilm ${ }^{\mathrm{TM}}$ Aerobic Count (Petrifilm AC), milk plate count agar (MPCA) and tryptone soya agar (TSA). Most laboratories followed the older versions NMKL 86:2006 and ISO 4833:2003, which have been replaced by NMKL 86:2013 and ISO 4833-1:2013 respectively. The incubation conditions are otherwise similar, and both the NMKL and ISO methods prescribe incubation for 72 h at $30^{\circ} \mathrm{C}$. For users of Petrifilm AC the incubation conditions depend on the method - for example AFNOR 3M 01/1-09/89 prescribes incubation for 72 h at $30^{\circ} \mathrm{C}$, whereas AOAC® 990.12 prescribes 48 h at $35^{\circ} \mathrm{C}$.

For the analysis at $20^{\circ} \mathrm{C}$ two laboratories followed NMKL 184. This is a method for aerobic count and specific spoilage organisms in fish and fish products, and uses incubation on iron agar (IA).

For the analysis at $30^{\circ} \mathrm{C}$ three laboratories used analyses based on the TEMPO ${ }^{\circledR}$ (bioMérieux ${ }^{\circledR}$ SA, Marcy l`toile, France) system, either TEMPO ${ }^{\circledR}$ AC or TEMPO ${ }^{\circledR}$ TVC. With these methods the sample is incubated in a card that contains wells with different volumes. A substrate in the card emits fluorescence when hydrolysed by the microorganisms. The determination of the number of microorganisms is based on MPN (Most Probable Number) and on the emitted fluorescence.

## Contaminating microorganisms in dairy products

## Mixture A

As in the analysis of aerobic microorganisms at $20^{\circ} \mathrm{C}$ and $30^{\circ} \mathrm{C}$ strains of Micrococcus sp., Klebsiella pneumoniae and Enterococcus hirae were target organisms. The results were distributed around a fairly distinct peak. The results from one laboratory was clearly lower than the rest, and should be considered an outlier. No false negative results were reported.

## Mixture B

As in the analysis of aerobic microorganisms at $20^{\circ} \mathrm{C}$ and $30^{\circ} \mathrm{C}$ strains of Escherichia coli, Serratia marcescens and Staphylococcus hyicus were target organisms. The results were distributed around a fairly distinct peak. The results from one laboratory was clearly lower than the rest, and should be considered an outlier. No false negative results were reported.

## Mixture C

As in the analysis of aerobic microorganisms at $20^{\circ} \mathrm{C}$ and $30^{\circ} \mathrm{C}$ strains of Providencia alcalifaciens, Staphylococcus aureus and Bacillus cereus were target organisms. The results were distributed around a distinct and narrow peak. The results from one laboratory was clearly lower than the rest, and should be considered an outlier. No false negative results were reported.

## General remarks

Only 17 laboratories performed the analysis, which is therefore not evaluated statistically. Median values are therefore also shown instead of mean values in the table and figures below. The results are in general however in agreement with the concentrations determined in the analyses at the National Food Agency (Table 3).

The aim of the analysis is to identify potential contaminating bacteria in dairy products. Here nine of the 17 laboratories ( $53 \%$ ) stated that they followed the standard method ISO 13559:2002 / IDF 153:2002, while one laboratory used the older IDF 153:1991. The remaining laboratories either followed internal methods, or did not specify which method they used. All 17 laboratories however stated that they used sugar-free agar (SFA).

According to ISO 13559:2002 / IDF 153:2002, lactic acid bacteria are not classified as contaminating microorganisms in dairy products. Lactic acid bacteria are catalase negative, and can therefore be distinguished by a catalase test. Such as test is however not included in ISO 13559:2002 / IDF 153:2002, which only specifies the counting of colonies that are "characteristic contaminating microorganisms". Five of the nine laboratories that followed ISO 13559/IDF 153 stated that they performed a catalase test. No other laboratories stated that they performed a confirmation. No obvious difference can however be found in the results between laboratories that performed a confirmation and those that did not.

All three low outliers, one for each mixture, were reported by the same laboratory. According to ISO 13559:2002 / IDF 153:2002 small (pin-point) colonies shall be excluded in the enumeration of colonies. It is possible that laboratories have made different interpretations of "pin-point", and that this could lead to lower results for laboratories that include fewer colonies.

## A

B

C

A

B

C

## Enterobacteriaceae

## Mixture A

The strain of Klebsiella pneumoniae was target organism for the analysis. The results were distributed around a distinct peak, with three low and two high outliers. Three laboratories reported false negative results.

## Mixture B

The strains of Escherichia coli and Serratia marcescens were target organisms for the analysis. The results were distributed around a distinct peak, with four low and one high outlier. One laboratory reported a false negative result.

## Mixture C

The strain of Providencia alcalifaciens was target organism for the analysis. The results were distributed around a distinct peak, with five low outliers. Four laboratories reported false negative results.

## General remarks

The analyses were in general without problems for the 142 laboratories. The choice of method and medium had no effect on the outcome for either of the mixtures. Outliers and false negative results could not be attributed to the use of a specific method or medium.

Most laboratories reported following either NMKL 144:2005 (50 \%), 3M Petrifilm ( $21 \%$ ) or ISO 21528-2:2004 (17 \%). Two laboratories stated the use of ISO 215281:2004, which is a method based on MPN (Most Probable Number) for the analysis of Enterobacteriaceae. Both ISO 21528-1:2004 and ISO 21528-2:2004 have during 2017 been replaced by ISO 21528-1:2017 and ISO 21528-2:2017 respectively. The MPN method ISO 21528-1:2017 is recommended when the expected concentration of Enterobacteriaceae is lower than 100 cfu/gram.

Enterobacteriaceae are Gram-negative and oxidase negative bacteria, that ferment glucose with the production of acid by-products. On violet red bile glucose agar (VRBG) - which is used in both NMKL 144 and ISO 21528-2 - they form pink/red colonies, with or without a bile precipitation zone. The appearance is similar on $3 \mathrm{M}^{\mathrm{TM}}$ Petrifilm ${ }^{\mathrm{TM}}$ Enterobacteriaceae (Petrifilm EB), which also includes a colour indicator that assists in the detection of acid by-products, and a plastic film for detection of gas production.

NMKL 144:2005 stipulates that presumptive colonies on VRBG shall be confirmed with an oxidase test. In contrast, ISO 21528-2:2004 states that presumptive colonies shall be confirmed with both an oxidase test and a test of glucose fermentation. In the revised ISO 21528-2:2017 the confirmation has been changed somewhat. In the new method, glucose agar has been replaced by glucose oxidation/fermentation (OF) medium. Colonies that are oxidase negative and that produce acid from glucose in the OF medium are confirmed as Enterobacteriaceae.

In total, 90 of the 142 laboratories ( $63 \%$ ) stated they performed some kind of confirmation, most commonly an oxidase test. Confirmation does not appear to have had an effect on the outcome. Rather, laboratories that did not perform a confirmation as a whole reported fewer false negative results and outliers compared to laboratories that performed a confirmation.

As in the analysis of aerobic microorganisms a small number of laboratories used fluorescence-based methods (TEMPO® Enterobacteriaceae). Though the results from this method appeared to be somewhat higher compared to VRBG and Petrifilm EB, users of TEMPO® reported neither outliers nor false positive results. The number of laboratories that used TEMPO® is at the same time too small to be thoroughly evaluated in this report.

C

A

B

C

Coliform bacteria, $30^{\circ} \mathrm{C}$ and $37^{\circ} \mathrm{C}$

## Mixture A

The strain of Klebsiella pneumoniae was target organism for the analysis at both $30^{\circ} \mathrm{C}$ and $37^{\circ} \mathrm{C}$. The results for the analysis at $30^{\circ} \mathrm{C}$ were distributed around a distinct peak. One low and two high outliers were reported. One laboratory reported a false negative result.

The results at $37^{\circ} \mathrm{C}$ were also distributed around a distinct peak. At this temperature no outliers could be identified, but one laboratory reported a false negative result.

## Mixture B

The strain of Escherichia coli was target organism for the analysis both at $30^{\circ} \mathrm{C}$ and at $37^{\circ} \mathrm{C}$. The results for the analysis at $30^{\circ} \mathrm{C}$ were distributed around a distinct but somewhat wide peak. Two low and one high outlier were reported. One laboratory reported a false negative result.

The results at $37^{\circ} \mathrm{C}$ were also distributed around a somewhat wide peak, in which a smaller peak could possibly be seen for results with lower concentrations. No outliers could however be identified. In addition to E. coli, the mixture also contained a strain of Staphylococcus hyicus, and a strain of Serratia marcescens. S. hyicus is Gram-positive and should normally not grow on violet red bile agar (VRB) which was the most commonly used medium. S. marcescens is a weak fermenter of lactose and could therefore possibly form small colonies on VRB. The strain was present in the mixture at a concentration corresponding to that of the smaller peak (approximately $\log _{10} 3.7$ $\mathrm{cfu} / \mathrm{ml}$ ). At the National Food Agency two types of colonies were observed on VRB; large typical colonies of E. coli, and somewhat smaller colonies of likely S. marcescens. The smaller colonies were present in lower numbers, and were distinguished during the confirmation since they did not form gas in brilliant green lactose bile broth (BGLB). The results in the smaller peak were however reported both by laboratories that reported performing a confirmation, as well as laboratories that did not. Two laboratories reported false negative results for the analysis at $37^{\circ} \mathrm{C}$.

## Mixture C

No target organism for the analysis was present in mixture C. The mixture did however contain a strain of Providencia alcalifaciens, which is false positive for the analysis. Nine of 55 laboratories reported false positive results at $30^{\circ} \mathrm{C}$ and 15 of 91 laboratories at $37^{\circ} \mathrm{C}$. The majority of the false positive results were for concentrations around $\log _{10}$ $4.7 \mathrm{cfu} / \mathrm{ml}$, and corresponding to the concentration of $P$. alcalifaciens in the mixture. Not performing a confirmation appears to have contributed to the reporting of false positive results. As a whole, $73 \%\left(30^{\circ} \mathrm{C}\right)$ and $48 \%\left(37^{\circ} \mathrm{C}\right)$ of the laboratories reported performing some type of confirmation. Among those that reported false positive results, the corresponding number were in only $33 \%\left(30^{\circ} \mathrm{C}\right)$ and $27 \%\left(37^{\circ} \mathrm{C}\right)$.

## General remarks

Coliform bacteria are Gram-negative rods that ferment lactose with the production of gas and acid by-products. On VRB they form characteristic red colonies, due to uptake of crystal violet and neutral red from the medium. A red/pink zone of precipitation is normally also formed due to the precipitation of bile salts when the pH decreases.

Further, the presence of bile salts and crystal violet in VRB inhibit the growth of Grampositive microorganisms.

Most laboratories reported following either NMKL 44:2005 (28 \%), ISO 4832:2006 ( $26 \%$ ), or the use of $3 \mathrm{M}^{\mathrm{TM}}$ Petrifilm ${ }^{\mathrm{TM}}$ ( $24 \%$ ). Both NMKL 44:2005 and ISO 4832:2006 stipulate incubation on VRB, but they differ somewhat in the confirmation step. NMKL 44:2004 states that all presumptive colonies on VRB shall be confirmed in BGLB, while ISO 4832:2006 states that only atypical colonies need to be confirmed. Further, if the sample is suspected to contain stressed coliform bacteria, NMKL 44:2004 recommends pre-incubation on tryptone soya agar (TSA). $3 \mathrm{M}^{\mathrm{TM}}$ Petrifilm ${ }^{\mathrm{TM}}$ Coliform Count (Petrifilm CC) is also based on VRB, and in addition includes a plastic film that facilitates detection of gas production.

Lauryl sulphate broth (LSB) in combination with BGLB was used by laboratories that followed ISO 4831:2006 and NMKL 96 (different versions). ISO 4831:2006 is based on MPN (Most Probable Number) and is suitable to use when the expected concentration of coliform bacteria is lower than or equal to $100 \mathrm{cfu} / \mathrm{g}$. NMKL 96 is also based on MPN, and is adapted for the analysis of coliform bacteria in fish and seafood. It is recommended when the expected concentration of microorganisms is lower than or equal to $300 \mathrm{cfu} / \mathrm{g}$.

For the analysis at $37^{\circ} \mathrm{C}$ three laboratories used RAPID'E. coli 2 agar, which is a chromogenic medium that detects $\beta$-glucuronidase and $\beta$-galactosidase activity. On this medium coliform bacteria (Gal+/Gluc-) form blue/green colonies, while E.coli (Gal+/Gluc+) form pink/purple colonies. At the same temperature, two laboratories used Brilliance ${ }^{\mathrm{TM}}$ E. coli/coliform selective agar (Brilliance).

The mean values for TSA/VRB ( $30^{\circ} \mathrm{C}$ and $37^{\circ} \mathrm{C}$ ) and LSB/BGLB ( $37^{\circ} \mathrm{C}$ ) differed somewhat from other media. These two media were however only used by five laboratories each, and it cannot be ruled out that the differences are due to random variation. Pre-incubation on TSA could however have contributed to the somewhat higher mean values for TSA/VRB.

A

B

B

## Thermotolerant coliform bacteria

## Mixture A

The strain of Klebsiella pneumoniae was target organism for the analysis of thermotolerant coliform bacteria. The results were distributed around a distinct peak. No outliers could be identified, but two laboratories reported false negative results.

No target organism for the analysis of E. coli was present in mixture A. Despite this, three laboratories reported false negative results.

## Mixture B

The strain of Escherichia coli was target organism for the analysis of both thermotolerant coliform bacteria and E.coli. The results for thermotolerant coliform bacteria were distributed around a distinct peak, and two low outliers were reported. No false negative results were reported.

The results for the analysis of $E$. coli were distributed around a distinct but somewhat wide peak, with a tail of low outliers. In total six low and one high outlier were reported, as well as two false negative results. The outliers could not be attributed to the use of a specific method or medium. Outliers and false negative results were further reported both by laboratories that performed a confirmation test, as those that did not. The differences in incubation temperatures (mainly $37^{\circ} \mathrm{C}$ or $44^{\circ} \mathrm{C}$ ) that were used by the laboratories did not appear to have an effect on the outcome.

## Mixture C

No target organism was present in mixture C, neither for the analysis of thermotolerant coliform bacteria nor for E. coli. Despite this, two false positive results were reported for thermotolerant coliform bacteria. All laboratories that analysed E. coli however correctly reported negative results.

## General remarks

As a whole, the analyses were without problem for the laboratories. No obvious differences based on the use of a specific method or medium could be seen in the analysis of thermotolerant coliform bacteria. Confirmation also did not appear to have had an effect on the outcome, neither for thermotolerant coliform bacteria nor for E. coli. As in the previous proficiency testing round (October 2016) several laboratories however reported unclear or ambiguous method information for the analysis of E. coli. Simultaneously, for this analysis several media were used by two or fewer laboratories,
and hence the group of "Other" is rather large. This also means that comparisons between different methods and media are more general for this analysis.

The most used method in both analyses was NMKL 125:2005. It describes the analysis of both thermotolerant coliform bacteria and of E.coli. The method defines thermotolerant coliform bacteria as those that form typical dark red colonies surrounded by a zone of precipitation on VRB after incubation for 24 h at $44^{\circ} \mathrm{C}$. Presumptive colonies are confirmed by inoculation either in E. coli-broth (EC) or in lactose tryptone lauryl sulphate broth (LTLSB). In both of these media, thermotolerant coliform bacteria produce gas as a consequence of lactose fermentation. E. coli are further defined as those thermotolerant coliform bacteria that also produce indole either in LTLSB or in tryptone broth.

NMKL 125:2005 was the most used method also for the analysis of E. coli. It was followed by $3 \mathrm{M}^{\mathrm{TM}}$ Petrifilm ${ }^{\text {TM }}$ and ISO 16649-2:2001. In ISO 16649-2:2001 E. coli are defined as those bacteria that form typical blue colonies on tryptone bile X-glucuronide agar (TBX) after $18-24 \mathrm{~h}$ at $44^{\circ} \mathrm{C}$. The colonies are stained blue due to the reaction between E.coli $\beta$-glucuronidase and an indicator in the medium. No further confirmation of $\beta$-glucuronidase positive colonies is required according to ISO 16649-2:2001. $3^{\mathrm{TM}}$ Petrifilm ${ }^{\mathrm{TM}}$ EC/CC and $3 \mathrm{M}^{\mathrm{TM}}$ Petrifilm ${ }^{\mathrm{TM}}$ SEC are also based on media that detect E. coli $\beta$-glucuronidase activity. Further, the plastic film in Petrifilm EC/CC and Petrifilm SEC facilitates the detection of gas production due to lactose fermentation. Here, it should also be mentioned that NMKL 125 is currently being revised, and the new version will likely be more similar to ISO 16649-2.

In the analysis of E. coli, several of the reported methods were used only by a small number of laboratories. Four laboratories used methods based on the detection of fluorescence (TEMPO® E. coli). Three laboratories followed NMKL 96 (different versions) which is an MPN-based method adapted for the analysis of coliform bacteria, thermotolerant coliform bacteria and E. coli in fish and seafood. Three laboratories followed ISO 7251:2005, which is another MPN-based method for the detection of E. coli.

As in previous proficiency testing rounds, in the analysis of $E$. coli the results were somewhat lower for TBX, and somewhat higher for TSA/VRB, compared to other media. A possible explanation could be if the samples were been pre-incubated or not. If the presence of stressed microorganisms in the sample is suspected, ISO 16649-2:2001 stipulates that a pre-incubation should be carried out at $37^{\circ} \mathrm{C}$ for 4 h , before the final incubation at $44^{\circ} \mathrm{C}$ for $18-24 \mathrm{~h}$. In comparison, a similar pre-incubation is routinely carried out in NMKL 125:2005 (1-2 h on TSA at $20-25^{\circ} \mathrm{C}$ ) prior to the final incubation on VRB. However the differences were small and, as mentioned above, the method data was unclear or ambiguous for several laboratories. The results were at the same time fairly spread out, especially for Petrifilm EC/CC and TBX.

B

B

## Presumptive Bacillus cereus

## Mixture A

No target organism for the analysis was present in mixture A. Two laboratories reported false positive results.

## Mixture B

No target organism for the analysis was present in mixture A. Two laboratories reported false positive results. Likely, they have detected either Serratia marcescens (approximately $\log _{10} 3.7 \mathrm{cfu} / \mathrm{ml}$ in the mixture) or Staphylococcus hyicus (approximately $\log _{10} 4.3 \mathrm{cfu} / \mathrm{ml}$ in the mixture).

## Mixture C

The stain of Bacillus cereus was target organism for the analysis. The results for the 117 laboratories that performed the analysis were distributed around as distinct peak. Four low outliers were reported, as well as four false negative results.

## General remarks

As a whole, the analyses were without major problems for the laboratories. The exceptions were the low outliers and the false negative results for mixture C. No obvious explanation could be found for the false negative results. It can however be noted that all four of the low outliers were reported by laboratories that did not perform a confirmation. At the same time, performing or not performing a confirmation does not appear to have had an effect on the outcome for mixtures A and B.

Most laboratories followed either NMKL 67:2010 (56 \%) or ISO 7932:2004 (22 \%). One laboratory used the older NMKL 67:2003. The remaining methods were either internal methods, method that were not specified, or methods that were only used by a few laboratories.

The most commonly used method NMKL 67:2010 is based on incubation on blood agar (BA). On BA, B. cereus forms large irregular grey colonies, that are surrounded by a large zone of haemolysis. Suspected colonies are confirmed either on Bacillus cereusselective agar (BcsA) or on Cereus-Ident agar (a chromogenic medium). On BcsA presumptive B. cereus form bluish colonies that are surrounded by a zone of precipitation, due to lecithinase activity on egg yolk present in the medium. On CereusIdent agar, presumptive $B$. cereus are blue/turqoise and possibly surrounded by a blue ring. The colour is a result of $B$. cereus phosphatidylinositol phospholipase C (PI-PLC) cleavage of the chromogenic substrate X-myoinositol-1-phosphate present in Cereus-

Ident agar. In comparison, ISO 7932:2004 prescribes plating onto mannitol egg yolk polymyxin agar (MYP). On MYP, presumptive B. cereus form large pink colonies that are normally surrounded by a zone of precipitation, again as a consequence of lecithinase activity. The colonies are confirmed if they display haemolysis on BA.

An in previous proficiency testing rounds, the reported method data for the analysis of B. cereus was ambiguous for several laboratories. Several laboratories reported that the same medium was used in both steps in the analysis. Other laboratories reported combinations of method and media that were incompatible. As a general rule, the tables and figures below are based on the methods/media stated by the laboratories, regardless if these are compatible or not. In some cases it has however been assumed that the laboratory used the medium that is prescribed by the method. Laboratories that have only stated "chromogenic medium" are included in the group "Other".

Despite the uncertainties in the reporting of method data, the mean values for the different media are very similar, with two exceptions. Oxoid Brilliance ${ }^{\mathrm{TM}}$ Bacillus cereus agar (CBC) was used by a group of eight laboratories. CBC is a chromogenic medium, and cleavage of X-Gluc present in CBC by B. cereus $\beta$-glucuronidase results in white colonies with a blue/green centre. The mean value for CBC was slightly lower compared to other media, but at the same time users of this medium reported neither outliers nor false negative results. The mean value for MYP was also slightly lower compared to other media. The deviations for both CBC and MYP are however in the same range as the variations commonly found among media in the analysis of B. cereus (e.g. April 2017 and April 2016).

C

C

## Mixture A

No target organism for the analysis was present in mixture A. All of the 107 laboratories that performed the analysis correctly reported negative results.

## Mixture B

No target organism for the analysis was present in mixture B. Despite this, 17 laboratories reported positive results. The majority of these reported concentrations corresponding to that of Staphylococcus hyicus, which was present in the mixture at approximately $\log _{10} 4.3 \mathrm{cfu} / \mathrm{ml}$. At the National Food Agency, the strain formed grey/white colonies without a zone of precipitation on Baird-Parker agar with rabbit plasma fibrinogen ( $\mathrm{BP}+\mathrm{RPF}$ ). In subsequent confirmation the strain displays no, or only weak, coagulase activity.

## Mixture C

The strain of Staphylococcus aureus was target organism for the analysis. The results were distributed around a distinct peak. Six low and three high outliers were reported, as well as two false negative results.

## General remarks

As in previous proficiency testing rounds most laboratories (44 \%) reported following NMKL 66:2009. The remaining laboratories either followed ISO 6888-1:1999 (17 \%), used $3 \mathrm{M}^{\mathrm{TM}}$ Petrifilm ${ }^{\mathrm{TM}}$ Staph Express (15 \%) or followed ISO 6888-2:1999 (9 \%). Three laboratories used a fluorescence-based detection with TEMPO® STA.

NMKL 66:2009 prescribes incubation on BP and/or BP + RPF. The method also allows incubation on blood agar (BA) as a complement to these media. On BP, S. aureus forms characteristic convex shiny colonies, that have a grey/black colour due to reduction of tellurite in the medium. They are normally surrounded by a clear zone, due to proteolysis of egg yolk in the medium (lecithinase activity). An opaque halo may also form near the colony, due to precipitation caused by lipase activity. With NMKL 66 the colonies are confirmed by a positive result in a coagulase test. When BP + RPF is used, the coagulase activity is tested directly in the medium, and no further confirmation is required according to the method. Similar to NMKL 66, ISO 6888-1 stipulates plating onto BP and confirmation with a coagulase test, whereas ISO 6888-2 is based on BP + RPF. 3M $^{\text {TM }}$ Petrifilm ${ }^{\text {TM }}$ Staph Express (Petrifilm Staph) uses a modified BairdParker medium, and also contains a chromogenic indicator that stains colonies of S. aureus red/purple.

As a whole, the analyses were without problem for the laboratories. The exception was the large number of positive results reported for mixture $B$. These are likely a consequence of the characteristics of the particular strain that was used. S. hyicus is normally included among coagulase-positive Staphylococci, but the strain present in mixture B is in tests at the National Food Agency coagulase-negative, or only weakly coagulase-positive. Traditionally, coagulase-positive Staphylococci are confirmed by detection of extracellular or bound coagulase (tube coagulase test and slide coagulase test respectively). Another common confirmation is a latex agglutination test. This is based on latex particles coated either with fibrinogen or with IgG that binds to protein A on the bacterial cell surface. Antibodies targeted against polysaccharides on the bacterial cell surface are also used in variations of this test. The majority of the positive
results in mixture B were reported by laboratories that used Petrifilm Staph, whereof most reported performing a confirmation with $3 \mathrm{M}^{\mathrm{TM}}$ Petrifilm ${ }^{\mathrm{TM}}$ Staph Express Disk (Petrifilm Disk). This is based on detection of extracellular DNase, which is produced by the majority of coagulase-positive S. aureus, but also by S. intermedius and S. hyicus. Toluidin blue O in the disks visualises DNase activity as a pink zone around the colonies. The current strain of S. hyicus is at the National Food Agency only characterised with media and confirmation methods based on rabbit plasma, and it cannot be ruled out that there is a variation in how it performs on other types of media and with other methods for confirmation. In conclusion, both negative results based on confirmation with a coagulase test, and positive results based on confirmation with Petrifilm Disk should therefore be considered correct. Due to the characteristics of the strain the results for mixture B are not evaluated further, and no z values are calculated for the analysis. The results for mixture B are also not included in the tables below the box plots.

## C

C

## Mixture A

The strain of Enterococcus hirae was target organism for the analysis. The results for the 72 laboratories that performed the analysis were distributed around a distinct peak. Three low and six high outliers were reported, as well as one false negative result.

## Mixture B

No target organism for the analysis was present in mixture B. One laboratory reported a false negative result.

## Mixture C

No target organism for the analysis was present in mixture C. All laboratories that performed the analysis correctly reported negative results.

## General remarks

As a whole, the analysis was without major problems for the laboratories, with the exception of a fairly high number of outliers for mixture A. The choice of method or media had no effect on the outcome for either of the mixtures. Confirmation also did not appear to have an effect on the outcome.

NMKL 68:2011 was by far the most common method and was used by the majority of the laboratories ( $71 \%$ ). In addition to this, IDF 149A:1997 was used by four laboratories ( $6 \%$ ) and ISO 7899-2:2000 by three laboratories ( $4 \%$ ). The remaining laboratories either used internal methods or did not specify which method they used.

Enterococci are in NMKL 68:2011 defined as Gram-positive, coagulase negative and oval cocci, that hydrolyse esculin at $44^{\circ} \mathrm{C}$. The method prescribes incubation on Slanetz \& Bartley Enterococcus-agar (ENT). On ENT, enterococci reduce the colourless substrate 2,3,5-trifenyltetrazolium chloride to red formazan and form slightly raised colonies with a pink/red/maroon colour. They can sometimes also have a colourless edge. When stressed enterococci are suspected (e.g. in frozen foods) a pre-incubation on TSA for two hours is recommended, followed by overlay with ENT. Distinctly dark red colonies with a typical morphology are counted as enterococci without further confirmation. Colonies with a faint pink/red colour are confirmed by plating onto bile esculin agar (BEA). On BEA the substrate esculin is hydrolysed by $\beta$-glucosidase present in enterococci, which results in the formation of esculetin and glucose. Esculetin together with iron ions present in the medium then form a black precipitate. Incubation on BEA is at vid $44^{\circ} \mathrm{C}$ and colonies that cause a blackening of the medium after 2-24 hours are counted as enterococci. Four laboratories analysed according to the drinking water method ISO 7899-2:2000, which is similar to NMKL 68:2001. The method is based on membrane filtering followed by incubation on ENT. Confirmation is, as in the NMKL method, by plating on BEA (possibly with the addition of azide), but incubation is only for 2 hours.

In addition to ENT, kanamycin esculin azide agar (KEAA) and COMPASS® Enterococcus agar were used by three laboratories each. KEAA was used by laboratories that followed IDF 149A:1997, and with this medium the hydrolysis of esculin is tested directly. Two of the three laboratories that used KEAA stated they also performed a subsequent confirmation, but did not specify this further. IDF 149:A:1997 has according to ISO also been replaced by ISO 27205:2010/IDF 149:2010. As with

BEA, COMPASS® Enterococcus Agar detects $\beta$-glucosidase activity, but the latter medium instead uses X -Gluc as substrate, resulting in the formation of blue colonies.

Results from analysis of Enterococci.

A

A

## Gram-negative bacteria in dairy products

## Mixture A

The strain of Klebsiella pneumoniae was target organism for the analysis. All eleven laboratories correctly reported positive results.

## Mixture B

The strains of Escherichia coli and Serratia marcescens were target organism for the analysis. All eleven laboratories correctly reported positive results.

## Mixture C

The strain of Providencia alcalifaciens was target organism for the analysis. All eleven laboratories correctly reported positive results.

## General remarks

The analysis was without problems for the laboratories. All eleven laboratories reported using violet red bile glucose agar (VRBG) as medium and nine laboratories reported following NMKL 192:2011.

The method in NMKL 192:2011 is used to detect recontamination of Gram-negative bacteria in pasteurised milk and cream. Gram-negative bacteria do not survive high temperature/short time pasteurisation (HTST), where the temperature is raised to $72{ }^{\circ} \mathrm{C}$ for at least 15 seconds. Presence of Gram-negative bacteria therefore indicates recontamination, something which may limit the shelf-life of the product. With NMKL

192:2011 the unopened package of milk/cream is incubated at $25^{\circ} \mathrm{C}$ for 24 h , or at room temperature for 28 h . Subsequently 10 and $100 \mu \mathrm{l}$, respectively, are plated onto VRBG at $30^{\circ} \mathrm{C}$ for 24 h . The presence of five or more colonies is considered a positive result. When needed, confirmation can be done with potassium hydroxide ( KOH ). Colonies are then transferred with a loop onto a glass slide with KOH , and colonies that after $5-10$ seconds form a viscous string are considered as Gram-negative.

## Outcome of the results of individual laboratory - assessment

The reported results of all participating laboratories are listed in Annex 1, together with the minimum and maximum accepted values for each analysis. Results that received a remark (false results and outliers) are highlighted in yellow, with bold font.

It is the responsibility of the participating laboratories to correctly report results according to the instructions. When laboratories incorrectly report their results, for example by stating "pos" or "neg" for quantitative analyses, the results cannot be correctly processed. Such incorrectly reported results are normally excluded. Inclusion and further processing of such results may still be done, after manual assessment in each individual case.

Z-scores (see below) for individual analyses are shown in Annex 2 and can be used as a tool by laboratories when following up on the results.

The laboratories are not grouped or ranked based on their results. The performance of a laboratory as a whole can only be evaluated from the number of false results and outliers that are listed in Annex 1 and below the box plots.

Information on the results processing and recommendations for follow-up work are given in the Scheme Protocol (2). Samples for follow-up can be ordered, free of charge via our website: www.livsmedelsverket.se/en/PT-extra

In order to allow comparison of the results from different analyses and mixtures, all results are transformed into standard values (z-scores). For quantitative analyses, a zscore is either positive or negative, depending on whether the individual result is higher or lower than the mean value calculated from all laboratory results for each analysis.

The box plots are based on the z-scores listed in Annex 2, and give a comprehensive view of the achievement of each laboratory. A small box, centred around zero, indicates the results of that individual laboratory, with false results excluded, are close to the general mean values calculated for all laboratory results. The range of $z$-scores is indicated by the size of the box and, for most laboratories, by lines and/or circles above and beneath the box. For each laboratory, the number of false results and outliers are also listed in the tables below the box plots.

## Box plots and numbers of deviating results for each laboratory

- Z-scores are calculated according to the formula: $z=(x-m) / s$, where $x$ is the result of the individual laboratory, $m$ is the mean of the results of all participating laboratories, and s is the standard deviation of the participating laboratories, after removing outliers and false results.
- Outliers are included in the figures after being calculated to $z$-scores in the same way as for other results.
- False results do not generate any z-scores, and are not included in "No. of results".
- Correct results for qualitative analyses and correct negative results for quantitative analyses without target organism generate a z -score of 0 .
- The laboratory median value is illustrated by a horizontal red line in the box.
- The box includes 50 \% of a laboratory's results ( $25 \%$ of the results above the median and $25 \%$ of the results below the median). The remaining $50 \%$ are illustrated by lines and circles outside the box.
- A circle is for technical reasons shown in the plot when a value deviates to certain degree* from the other values. This does not by itself indicate that the value is an outlier.
- $z$-scores $>+4$ and $<-4$ are positioned at +4 and -4 , respectively, in the plot.
- The background is divided by lines and shaded fields to simplify identifying the range in which the results are located.
* < [lowest value in the box $-1,5 \times$ (highest value in the box-lowest value in the box)] or $>$ [highest value in the box $+1,5 \times$ (highest value in the box - lowest value in the box)].

## Test material and quality control

## Test material

Each laboratory received three manufactured freeze-dried microbial mixtures, designated A-C. The test material was freeze-dried in portions of 0.5 ml in vials, as described by Peterz and Steneryd (3). Before analysing the samples, the contents of each vial had to be dissolved in 254 ml of sterile diluent. The organisms present in the mixtures are listed in Table 2.

Table 2. Microorganisms present in mixtures A-C.

| Mixture $^{\mathbf{1}}$ | Microorganism | Strain |  |
| :--- | :--- | :--- | :---: |
|  |  | SLV no. ${ }^{\mathbf{2}}$ | Reference $^{\mathbf{3}}$ |
| A | Enterococcus hirae | SLV-536 | CCUG 46536 |
|  | Klebsiella pneumoniae | SLV-186 | CCUG 45102 |
|  | Micrococcus sp. | SLV-055 | ATCC 9341 |

## Quality control of the mixtures

It is essential to have aliquots of homogeneous mixture and equal volume in all vials in order to allow comparison of all freeze-dried samples from one mixture. Quality control is performed on 10 randomly chosen vials in conjunction with manufacturing of the mixtures or on 5 vials if an "old" mixture was used and the last quality control was performed more than 6 months ago. Homogeneity of a mixture is approved if, for each analysis, the values obtained for the test of reproducibility (T) and the test "Index of dispersion" between vials ( $\mathrm{I}_{2}$ ) do not simultaneously exceed 2.6 and 2.0 , respectively. (For definitions of T and $\mathrm{I}_{2}$, see references 4 and 5 respectively.)

Table 3. Concentration mean ( $m$ ), $T$ and $I_{2}$ values from the quality control of the mixtures; $m$ is expressed in $\log _{10}$ cfu (colony forming units) per ml of sample.

## Annex 1 Results of the participating laboratories - October 2017

All results are in $\log _{10}$ cfu per ml sample. Results reported as "< value" have been regarded as zero. Results reported as "> value" are exluded from the calculations. A dash indicates the analysis was not performed. Outliers and false results are highlighted and summarized for each analysis at the end of the table.

Min = lowest reported resultThe results are not evaluated
$m=$ mean value
$\mathrm{s}=$ standard deviation

+ = false positive
F- = false negative
< = low outlier
$>=$ high outlie
< OK = lowest accepted value >OK = highest accepted value

## Annex 2 Z-scores of all participants - October 2017

$Z$-scores are calculated according to: $z=(x-m) / s$, where $x=$ result of the individual laboratory, $m=$ mean of the results of all participating laboratories, $s=$ standard deviation of the results of all participating laboratories. Correct negative results in quantitative analyses have obtained a $Z$-score of zero. False results do not generate a $Z$-score. $Z$-scores from outliers are not real $z$-scores, but are a practical means to express the results from outliers. Very low and high $z$-scores are limited to -4 and +4 respectively.
$\square 2<|z| \leq 3, \square|z|>3$

$\square$ The results are not evaluated

## Internal and external control for microbiological analyses of food and drinking water

All analytical activities require work of a high standard that is accurately documented. For this purpose, most laboratories carry out some form of internal quality assurance, but their analytical work also has to be evaluated by an independent party. Such external quality control of laboratory competence is commonly required by accreditation bodies and can be done by taking part in proficiency testing (PT).
In a proficiency test, identical test material is analysed by a number of laboratories using their routine methods. The organiser evaluates the results and compiles them in a report.

## The National Food Agency's PT program offers

$>$ External and independent evaluation of laboratories analytical competence.
> Improved knowledge of analytical methods with respect to various types of organisms.
> Expert support.
> Tool for inspections regarding accreditation.
> Free extra material for follow-up analyses.

For more information visit our website: www2.slv.se/absint

## The National Food Agency's reference material

As a complement to the proficiency testing, but without specific accreditation, the National Food Agency also manufactures a number of reference materials (RM) for internal quality control of food and drinking water microbiological analyses, including pathogens.

More information is available on our website: www.livsmedelsverket.se/en/RM-micro

[^0]:    ${ }^{1}$ The links between the mixtures and the randomised sample numbers are shown in Annex 1.
    ${ }^{2}$ Internal strain identification no. at the National Food Agency.
    ${ }^{3}$ Origin or culture collection (CCUG: Culture Collection University of Gothenburg, Sweden ; ATCC:
    American Type Culture Collection)

[^1]:    - No target organism and therefore no value
    ${ }^{1} \mathrm{n}=10$ vials analysed in duplicate
    ${ }^{2} n=5$ vials analysed in duplicate
